前言

Previous editions of Computer Networks And Internets have received incredibly positive reviews; I especially thank readers who have taken the time to write to me personally. In addition to students who use the text in courses, networking professionals have written to praise its clarity and describe how it helped them pass professional certification exams. Many enthusiastic comments have also arrived about foreign translations. The success is especially satisfying in a market glutted with networking books. This book stands out because of its breadth of coverage, logical organization, explanation of concepts, focus on the Internet, and appeal to both professors and students. In response to suggestions from readers and recent changes in networking, the new edition has been completely reorganized, revised, and updated. Descriptions of older technologies has been reduced or eliminated. Material on data communications, which is becoming an essential staple of networking courses, has been expanded and placed in Part II of the text. The networking chapters build on the data communication basics, and describe both wired and wireless networking. In addition, to emphasize the new 802.11 wireless standards, the discussion of wireless includes cellular telephone technologies because cellular systems currently offer data services and will soon be adopting Internet protocols. Recent discussions about networking courses have engendered a debate about the bottom-up or top-down approach. In bottom-up, a student learns the lowest-level details, and then learns how the next higher levels use the lower-levels to provide expanded functionality. In top-down, one starts with a high-level application and only learns enough of the next lower layer to understand how the application can operate. This text combines the best of each. The text begins with a discussion of network applications and the communication paradigms that the Internet offers. It allows students to understand the facilities the Internet provides to applications before studying the underlying technologies that implement the facilities. Following the discussion of applications, the text presents networking in a logical manner so a reader understands how each new technology builds on lower layer technologies. The text is intended for upper-division undergraduates or beginning graduate students, who have little or no background in networking. It does not use sophisticated mathematics, nor does it assume a knowledge of operating systems. Instead, the text defines concepts clearly, uses examples and figures to illustrate how the technology operates, and states results of analysis without providing mathematical proofs.

章节摘录

插图：File Scanning. The most straightforward approach to analyze content operates on entire files. File scanning is a well-known technique used by the security software installed on a typical PC. In essence, a file scanner takes a file as input and looks for patterns of bytes that indicate a problem. For example, many virus scanners look for strings of bytes known as a fingerprint. That is, a company that sells a virus scanner collects copies of viruses, places each in a file, finds sequences of bytes that are uncommon, and creates a list of all sequences. When a user runs virus scanner software, the software searches files on the user's disk to see if any file contains sequences of bytes that match items on the list. File scanning works well to catch common problems. Of course, file scanning can produce a false positive if an ordinary file happens to contain a string on the list, and can produce a false negative if a new virus exists that does not contain any of the strings on the list.

Deep Packet Inspection (DPI) . The second form of content analysis operates on packets instead of files. That is, instead of merely examining the headers in packets that pass into the site, a DPI mechanism also examines the data in the packet payload. Note that DPI does not exclude header examination — in many cases, the contents of a payload cannot be interpreted without examining fields in the packet header. As an example of DPI, consider an attack where a slight misspelling of a domain name is used to trick a user into trusting a site. An organization that wants to prevent such attacks can black-list a set of URLs that are known to be a security risk. The proxy approach requires every user at the site to configure their browser to use a web proxy (i.e, an intermediate web system that checks a URL before fetching the requested page) . As an alternative, a Deep Packet Inspection filter can be set up to inspect each outgoing packet and watch for an HTTP request to any of the black-listed sites. The chief disadvantage of DPI arises from computational overhead. Because a packet payload in an Ethernet frame can be over twenty times larger than a packet header, DPI can require twenty times more processing than header inspection. Furthermore, the payload is not divided into fixed fields, which means that DPI mechanisms must parse contents during an inspection.
