章节摘录

插图：In Figure 3 3, "Data entity" is not a pattern. It's a requirement pattern group: a place for describing the common features of the four patterns that build on it. Any descriptive information that applies to all patterns in a group should be given for the group, rather than repeated for each pattern. Also, by convention, labels for relationships between requirement patterns are placed nearer the subject of the relationship, rather than the object. So, it is a Data entity that has an ID (rather than vice versa) . The hexagonal shape of "Information storage" denotes it as an infrastructure. See the beginning of Part II of this book for a diagram of this sort for all the requirement patterns in this book. Each of the eight domain chapters contains a diagram of this sort in its introduction, with annotations giving a brief explanation of each pattern, pattern group, and infrastructure.

Requirement Pattern Classifications Requirements can be classified in various ways (for example, by dividing them into functional and nonfunctional ones) . Using requirement patterns has the advantage that if we classify the patterns, we automatically classify the requirements that use those patterns. Classifications tell us a little about the nature of the requirements that result from using each requirement pattern. Other ways of using these classifications include finding requirements according to their classification and producing statistics. People like statistics (some people, at least, and they tend to be senior executives it's worth our while keeping happy) . Statistics on the requirements for a system can be useful in a variety of ways. They, can give a rough picture of the scale and complexity of the system. To do this, we need to tag each requirement with whatever values are needed for all the sorts .
