## 章节摘录

An accidental discovery has brought seismologists (地震学家) one step closer to being able to predict earthquakes. As part of an unrelated effort to measure underground changes caused by shifts in barometric pressure , a team of researchers found that increases insubterranean (地下的) pressure came before earthquakes along Californias San Andreas Fault byas much as 10 hours. If follow-up tests advance the findings , seismologists (地震学家) may eventually be able to provide a few hours notice for people to find a safe haven prior to quakes. As the horrificimages from China demonstrate , the effort is well worth the alternative. "Predicting earthquakes is the final goal for seismologists , " says Fenglin Niu , there search teams lead author and a Rice University seismologist. "This is a start." The research team theorizes that the immensea mount of pressure building along the Fault causes mall cracks within the rock during the final hours before an earthquake , increasing rock density and slowing the transmission signals. "The morecracks you have , the slower the seismic velocity (震波速度) will be , " says study co-author Paul Silver , a geophysicist with the Carnegie Institution ofWashington. Still unknown is whether there is any significance to the fact that the magnitude-3 (三级) quake had a much longer pre-seismic signal than the lower-magnitude quake , or whether it wasimply because its magnitude was larger and its epicenter (震中) closer to the sensors. If scientists can flesh out the new findingsduring future earthquakes a two-year study at the same seismically active location begins thisSeptember-it could form the basis of a vastlyim proved early-warning system for quakes. Currentearthquake-warning systems give just a fewseconds notice because they find only P-waves , the fast-moving seismic waves that precede the more destructive waves released during a quake.Upgrading to a seismic stress meter (压力仪) , however , is still a long wav off.

### 媒体关注与评论

本套图书以“练”为主，讲练结合，并且按周次设计，非常符合课堂学习的需要；另外，题型多样，体现了中高考的命题趋势。
